

• Normalized Difference Red Edge (NDRE)

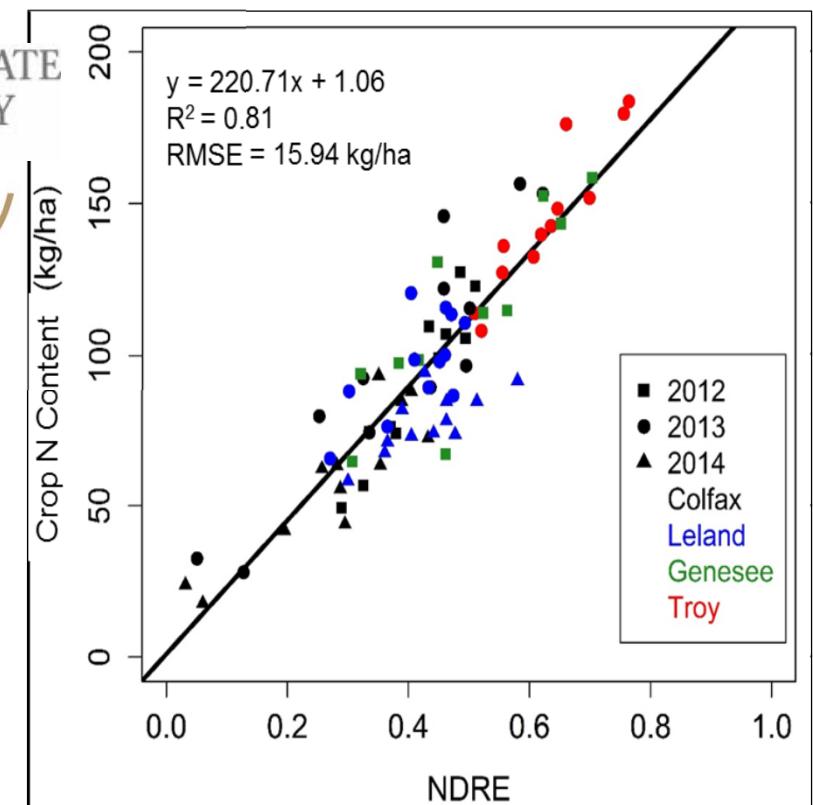

$$\frac{\text{NIR}-\text{Red.Edge}}{\text{NIR}+\text{Red.Edge}}$$

Troy
Magney

Mapping wheat canopy nitrogen content from RapidEye vegetation indices for post-harvest performance evaluation

Troy S. Magney ^{1,2*}, Jan U.H. Eitel ^{2,3}, and Lee A. Vierling ^{2,3} In review

- Four fields, 3 seasons, 12 calibration locations/field
- Above ground crop N at harvest correlated with NDRE at peak greenness.
- Patterns vary by year and crop.
- Highest production and N uptake in deeper soils, usually draws and flat upslope areas.

Cook Farm Field Day 2016

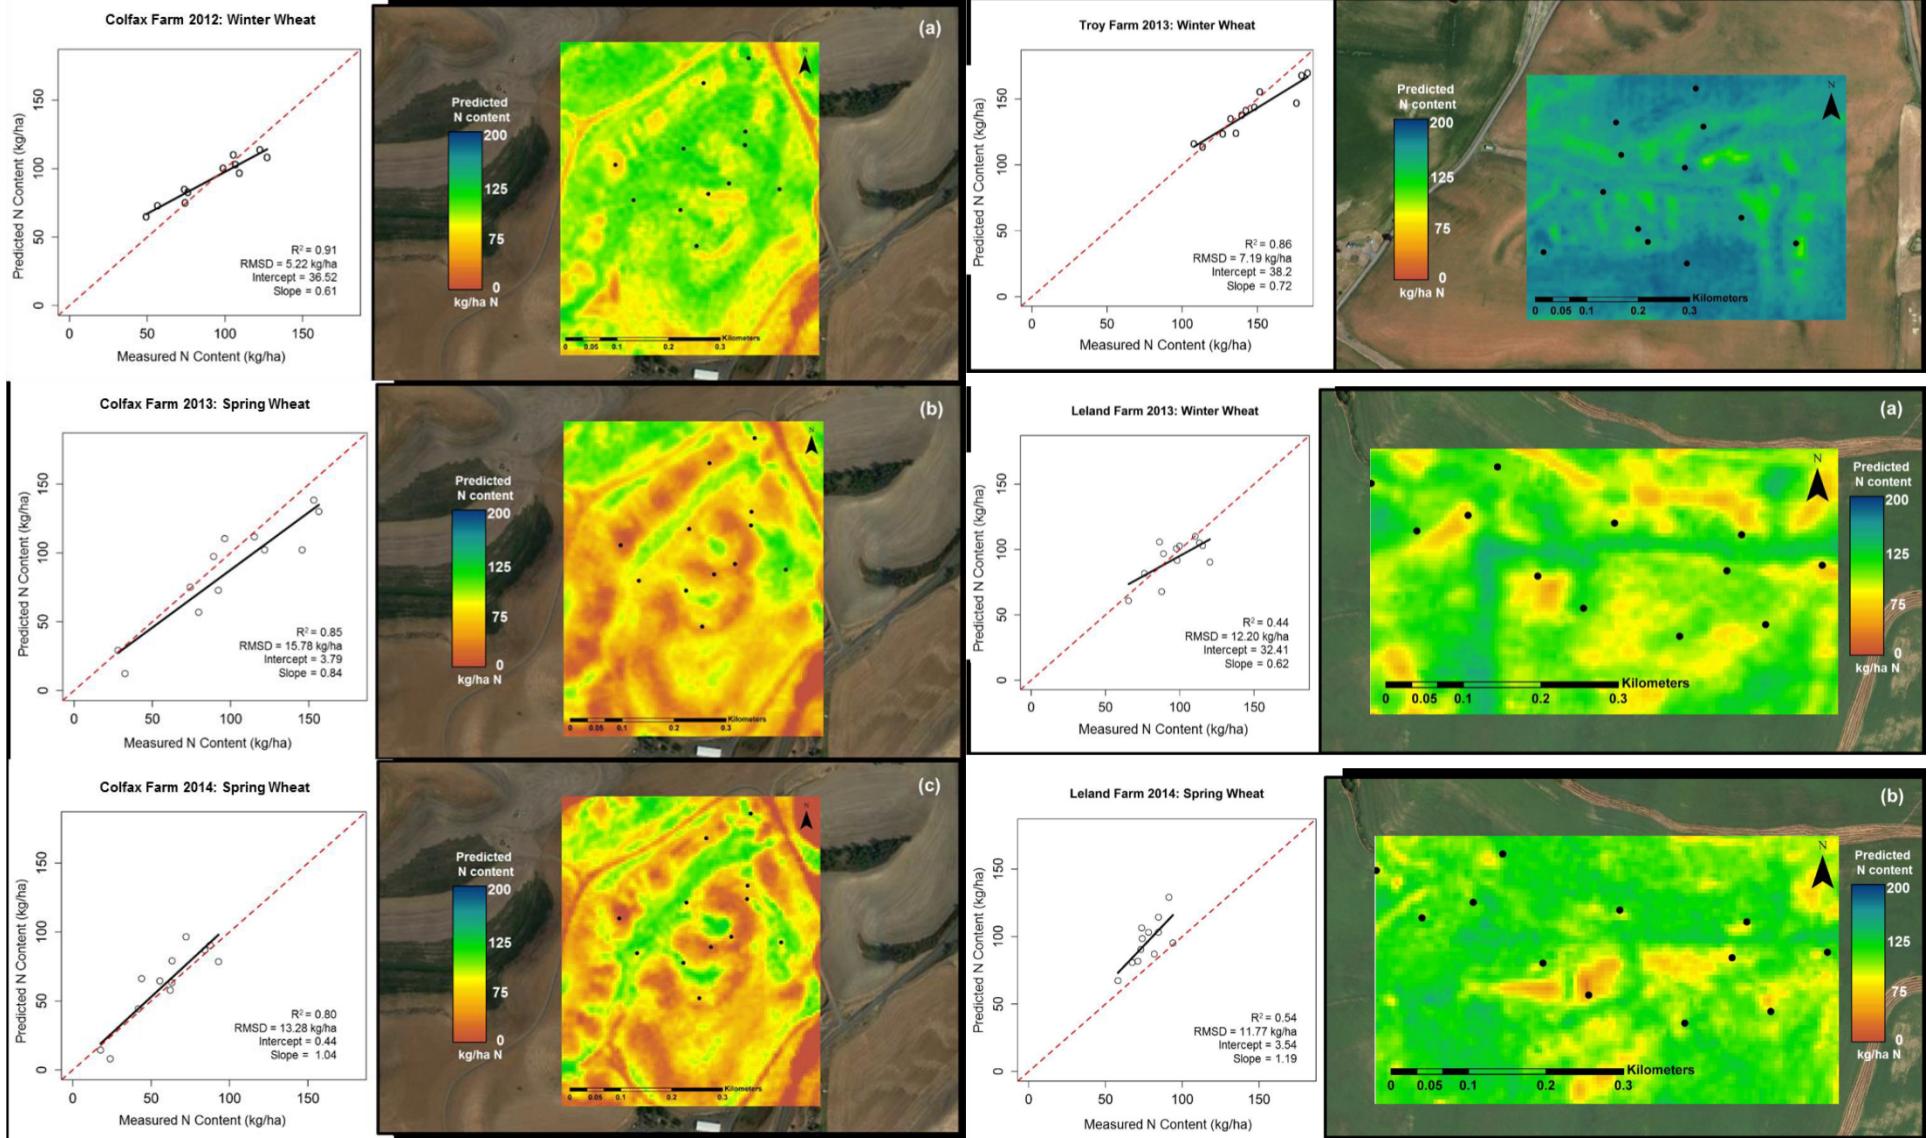

Remote & Proximal Sensing

Dave Brown

Contribution by Lee Vierling, Jan Eitel, Troy Magney, Erin Brooks, Matt Yourek, Caley Gasch & Matteo Poggio

- NDRE responds to both leaf area and nitrogen concentration in leaves (correlated with grain nitrogen).
- Some fields less variable than others (uniformly deep soils).

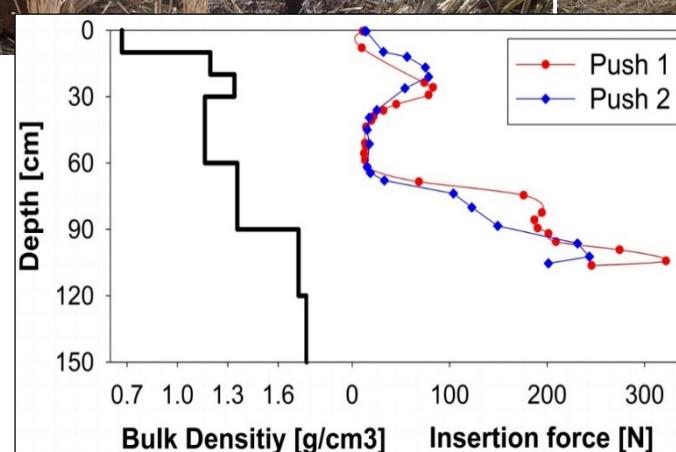

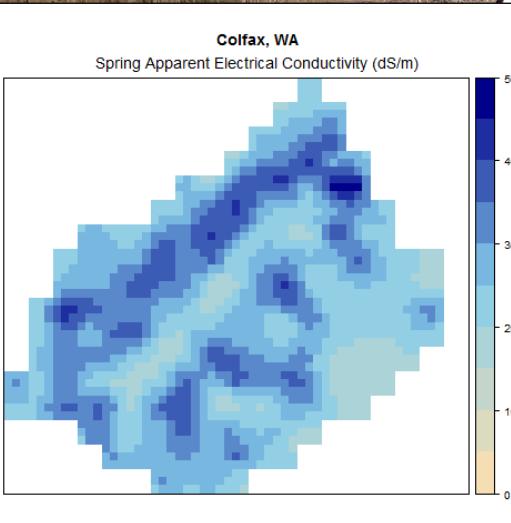

Contribution by Lee Vierling, Jan Eitel, Troy Magney, Erin Brooks, Matt Yourek, Caley Gasch & Matteo Poggio

- Soil water is primary control on spatial variability of yield.
- Effective soil thickness – depth to restrictive layer – controls hydrology.
- Proximal soil sensing used to map restrictive layers (high clay and/or bulk density).

Electrical Conductivity

Responds to soil:

- Salinity
- Water content
- Clay content

VisNIR penetrometer

Estimates:

- Clay content
- Bulk Density
- Organic Matter
